Abstract. The present contribution is concerned with the interpretability of fuzzy rule-based systems. While this property is widely considered to be a crucial one in fuzzy rule-based modeling, a more detailed investigation of what "interpretability" actually means is still missing. So far, interpretability has often been associated with heuristic assumptions about shape and mutual overlapping of fuzzy membership functions. In this chapter, we attempt to approach this problem from a more general and formal point of view. First, we clarify what, in our opinion, the different aspects of interpretability are. Following that, we propose an axiomatic framework for the interpretability of linguistic variables (in Zadeh's sense) which is underlined by examples and application perspectives.

1 Introduction

The epoch-making idea of L. A. Zadeh's early work was to utilize what he called "fuzzy sets" as mathematical models of linguistic expressions which cannot be represented in the framework of classical binary logic and set theory in a natural way. The introduction of his seminal article on fuzzy sets [37] contains the following remarkable words:

> "More often than not, the classes of objects encountered in the real physical world do not have precisely defined criteria of membership. [. . .] Yet, the fact remains that such imprecisely defined "classes" play an important role in human thinking, particularly in the domains of pattern recognition, communication of information, and abstraction."

Fuzzy systems became a tremendously successful paradigm – a remarkable triumph which started with well-selling applications in consumer goods implemented by Japanese engineers. The reasons for this development are manifold; however, we are often confronted with the following arguments:

1. The main difference between fuzzy systems and other control or decision support systems is that they are parameterized in an interpretable

way – by means of rules consisting of linguistic expressions. Fuzzy systems, therefore, allow rapid prototyping as well as easy maintenance and adaptation.

2. Fuzzy systems offer completely new opportunities to deal with processes for which only a linguistic description is available. Thereby, they allow to achieve a robust, secure, and reproducible automation of such tasks.

3. Even if conventional control or decision support strategies can be employed, re-formulating a system's actions by means of linguistic rules can lead to a deeper qualitative understanding of its behavior.

We would like to raise the question whether fuzzy systems, as they appear in daily practice, really reflect these undoubtedly nice advantages. One may observe that the *possibility to estimate the system's behavior by reading and understanding the rule base only* is a basic requirement for the validity of the above points. If we adopt the usual wide understanding of fuzzy systems (rule-based systems incorporating vague linguistic expressions), we can see, however, that this property – let us call it *interpretability* – is *not guaranteed by definition*.

In our opinion, interpretability should be *the* key property of fuzzy systems. If it is neglected, one ends up in nothing else than black-box descriptions of input-output relationships and any advantage over neural networks or conventional interpolation methods is lost completely.

The more fuzzy systems became standard tools for engineering applications, the more Zadeh's initial mission became forgotten. In recent years, however, after a relatively long period of ignorance, an increasing awareness of the crucial property of interpretability has emerged [1,2,6,9,17,34–36], where the present book is intended to bundle these forces by presenting a comprehensive overview of recent research on this topic. So far, the following questions have been identified to have a close connection to interpretability:

1. Does the inference mechanism produce results that are technically and intuitively correct?

2. Is the number of rules still small enough to be comprehensible by a human expert?

3. Do the fuzzy sets associated to the linguistic expressions really correspond to the human understanding of these expressions?

The first question has to be approached from the side of approximate reasoning [14–16] and relational equations [10,21,26]. There is no standard way to tackle the problems associated with the second question (see the introductory chapter of this book for an overview of different ideas).

The given chapter is solely devoted to the third question. So far, there is a shallow understanding that the third question is related to shape, ordering, and mutual overlapping of fuzzy membership functions. We intend to approach this question more formally. This is accomplished making the inherent relationships between the linguistic labels explicit by formulating

them as (fuzzy) relations. In order to provide a framework that is as general as possible, we consider linguistic variables in their most general form.

2   Preliminaries

Throughout the whole chapter, we do not explicitly distinguish between fuzzy sets and their corresponding membership functions. Consequently, uppercase letters are used for both synonymously. For a given non-empty set X, we denote the set of fuzzy sets on X with $\mathcal{F}(X)$. As usual, a fuzzy set $A \in \mathcal{F}(X)$ is called *normalized* if there exists an $x \in X$ such that $A(x) = 1$.

Triangular norms and conorms [24] are common standard models for fuzzy conjunctions and disjunctions, respectively. In this chapter, we will mainly need these two concepts for intersections and unions of fuzzy sets. It is known that couples consisting of a *nilpotent t-norm* and its dual t-conorm [18,24] are most appropriate choices as soon as fuzzy partitions are concerned [11,26]. The most important representatives of such operations are the so-called Łukasiewicz operations:

$$T_{\mathbf{L}}(x, y) = \max(x + y - 1, 0)$$
$$S_{\mathbf{L}}(x, y) = \min(x + y, 1)$$

The intersection and union of two arbitrary fuzzy sets $A, B \in \mathcal{F}(X)$ with respect to the Łukasiewicz operations can then be defined as

$$\bigl(A \cap_{\mathbf{L}} B\bigr)(x) = T_{\mathbf{L}}\bigl(A(x), B(x)\bigr) \quad \text{and}$$
$$\bigl(A \cup_{\mathbf{L}} B\bigr)(x) = S_{\mathbf{L}}\bigl(A(x), B(x)\bigr),$$

respectively. We restrict to these two standard operations in the following – for the reason of simplicity and the fact that they perfectly fit to the concept of fuzzy partitions due to Ruspini [33]; recall that a family of fuzzy sets $(A_i)_{i \in I} \subseteq \mathcal{F}(X)$ is called *Ruspini partition* if the following equality holds for all $x \in X$:

$$\sum_{i \in I} A_i(x) = 1$$

Furthermore, recall that a fuzzy set $A \in \mathcal{F}(X)$ is called *convex* if the property

$$x \leq y \leq z \implies A(y) \geq \min\bigl(A(x), A(z)\bigr)$$

holds for all $x, y, z \in X$ (given a crisp linear ordering $\leq$ on the domain X) [4,27,37].

Lemma 1. [4] *Let X be linearly ordered. Then an arbitrary fuzzy set $A \in \mathcal{F}(X)$ is convex if and only if there exists a partition of X into two connected subsets X_1 and X_2 such that, for all $x_1 \in X_1$ and all $x_2 \in X_2$, $x_1 \leq x_2$ holds and such that the membership function of A is non-decreasing over X_1 and non-increasing over X_2.*

As a trivial consequence of the previous lemma, a fuzzy set whose membership function is either non-decreasing or non-increasing is convex.

3   Formal Definition

Since it has more or less become standard and offers much freedom, in particular with respect to integration of linguistic modifiers and connectives, we closely follow Zadeh's original definition of linguistic variables [38–40].

Definition 1. A *linguistic variable* V is a quintuple of the form

$$V = (N, G, T, X, S),$$

where N, T, X, G, and S are defined as follows:

1. N is the name of the linguistic variable V
2. G is a grammar
3. T is the so-called *term set*, i.e. the set linguistic expressions resulting from G
4. X is the universe of discourse
5. S is a $T \to \mathcal{F}(X)$ mapping which defines the semantics – a fuzzy set on X – of each linguistic expression in T

In this chapter, let us assume that the grammar G is always given in *Backus-Naur Form (BNF)* [32].

In our point of view, the ability to interpret the meaning of a rule base qualitatively relies deeply upon an intuitive understanding of the linguistic expressions. Of course, this requires knowledge about inherent relationships between these expressions. Therefore, if qualitative estimations are desired, these relationships need to transfer to the underlying semantics, i.e. the fuzzy sets modeling the labels. In other words, interpretability is strongly connected to the preservation of inherent relationships by the mapping S (according to Def. 1).

The following definition gives an exact mathematical formulation of this property.

Definition 2. Consider a linguistic variable $V = (N, T, X, G, S)$ and an index set I. Let $R = (R_i)_{i \in I}$ be a family of relations on the set of verbal values T, where each relation R_i has a finite arity a_i. Assume that, for every relation R_i, there exists a relation Q_i on the fuzzy power set $\mathcal{F}(X)$ with the same arity.[1] Correspondingly, we abbreviate the family $(Q_i)_{i \in I}$ with Q. Then the linguistic variable V is called *R-Q-interpretable* if and only if the following holds for all $i \in I$ and all $x_1, \ldots, x_{a_i} \in T$:

$$R_i(x_1, \ldots, x_{a_i}) \implies Q_i(S(x_1), \ldots, S(x_{a_i})) \tag{1}$$

---

[1] Q_i is associated with the "semantic counterpart" of R_i, i.e. the relation that models R_i on the semantical level.

Remark 1. The generalization of Def. 2 to fuzzy relations is straightforward. If we admit fuzziness of the relations R_i and Q_i, the implication in (1) has to be replaced by the inequality

$$R_i\big(x_1, \ldots, x_{a_i}\big) \leq Q_i\big(S(x_1), \ldots, S(x_{a_i})\big).$$

4   A Detailed Study by Means of Practical Examples

In almost all fuzzy control applications, the domains of the system variables are divided into a certain number of fuzzy sets by means of the underlying ordering – a fact which is typically reflected in expressions like "small", "medium", or "large". We will now discuss a simple example involving orderings to illustrate the concrete meaning of Def. 2.

Let us consider the following linguistic variable:

$$V = (\text{"v1"}, G, T, X, S)$$

The grammatical definition G is given as follows:

$$
\begin{aligned}
\bot &:= \langle \text{atomic} \rangle \ ; \\
\langle \text{atomic} \rangle &:= \langle \text{adjective} \rangle \mid \langle \text{adverb} \rangle \ \langle \text{adjective} \rangle \ ; \\
\langle \text{adjective} \rangle &:= \text{"small"} \mid \text{"medium"} \mid \text{"large"} \ ; \\
\langle \text{adverb} \rangle &:= \text{"at least"} \mid \text{"at most"} \ ;
\end{aligned}
$$

Obviously, the following nine-element term set can be derived from G:

$$
\begin{aligned}
T = \{ &\text{"small"}, \text{"medium"}, \text{"large"}, \\
&\text{"at least small"}, \text{"at least medium"}, \\
&\text{"at least large"}, \text{"at most small"}, \\
&\text{"at most medium"}, \text{"at most large"} \}
\end{aligned}
$$

The universe of discourse is the real interval $X = [0, 100]$.

Taking the "background" or "context" of the variable into account, almost every human has an intuitive understanding of the qualitative meaning of each of the above linguistic expressions, even if absolutely nothing about the quantitative meaning, i.e. the corresponding fuzzy sets, is known. This understanding, to a major part, can be attributed to elementary relationships between the linguistic values. According to Def. 2, let us assume that these inherent relationships are modeled by a family of relations $R = (R_i)_{i \in I}$.

In our opinion, the most obvious relationships in the example term set T are orderings and inclusions. Therefore, we consider the following two binary relations (for convenience, we switch to infix notations here):

$$R = (\preceq, \sqsubseteq) \tag{2}$$

The first relation $\preceq$ stands for the ordering of the labels, while the second one corresponds to an inclusion relation, e.g. $u \sqsubseteq v$ means that v is a more general term than u.

First of all, one would intuitively expect a proper ordering of the adjectives, i.e.

$$\text{“small”} \preceq \text{“medium”} \preceq \text{“large”}. \tag{3}$$

Moreover, the following monotonicities seem reasonable for all adjectives u, v (atomic expressions from the set {"small", "medium", "large"}):

$$u \sqsubseteq \text{“at least” } u$$
$$v \sqsubseteq \text{“at most” } v$$
$$u \preceq v \Longrightarrow \text{“at least” } u \preceq \text{“at least” } v$$
$$u \preceq v \Longrightarrow \text{“at most” } u \preceq \text{“at most” } v$$
$$u \preceq v \Longrightarrow \text{“at least” } v \sqsubseteq \text{“at least” } u$$
$$u \preceq v \Longrightarrow \text{“at most” } u \sqsubseteq \text{“at most” } v$$

Figures 1 and 2 show Hasse diagrams which fully describe the two relations $\preceq$ and $\sqsubseteq$ (note that both relations are supposed to be reflexive, a fact which, for the sake of simplicity, is not made explicit in the diagrams).

Fig. 1. Hasse diagram of ordering relation $\preceq$

Now we have to define meaningful counterparts of the relations in R on the semantical level, i.e. on $\mathcal{F}(X)$. We start with the usual inclusion of fuzzy sets according to Zadeh [37].

Definition 3. Consider two fuzzy sets of $A, B \in \mathcal{F}(X)$. A is called a *subset* of B, short $A \subseteq B$, if and only if, for all $x \in X$, $A(x) \leq B(x)$. Consequently, in this case, B is called a *superset* of A.

For defining a meaningful counterpart of the ordering relation $\preceq$, we adopt a simple variant of the general framework for ordering fuzzy sets proposed in [4,5], which includes well-known orderings of fuzzy numbers based on the extension principle [23,25].
Fig. 2. Hasse diagram of inclusion relation $\sqsubseteq$

Definition 4. Suppose that a universe X is equipped with a crisp linear ordering $\leq$. Then a preordering $\precsim$ of fuzzy sets can be defined by

$$A \precsim B \iff \big(\text{ATL}(B) \subseteq \text{ATL}(A) \text{ and } \text{ATM}(A) \subseteq \text{ATM}(B)\big),$$

where the operators ATL and ATM are defined as follows:

$$\text{ATL}(A)(x) = \sup\{A(y) \mid y \leq x\}$$
$$\text{ATM}(A)(x) = \sup\{A(y) \mid y \geq x\}$$

Figure 3 shows an example what the operators ATL and ATM give for a non-trivial fuzzy set. It is easy to see that ATL always yields the smallest superset with non-decreasing membership function, while ATM yields the smallest superset with non-increasing membership function. For more details about the particular properties of the ordering relation $\precsim$ and the two operators ATL and ATM, see [4,5].

Summarizing, the set of counterpart relations Q looks as follows (with the relations from Defs. 3 and 4):

$$Q = (\precsim, \subseteq) \tag{4}$$

Now R-Q-interpretability of linguistic variable V (with definitions of R and Q according to (2) and (4), respectively) specifically means that the following two implications hold for all $u, v \in T$:

$$u \preceq v \implies S(u) \precsim S(v) \tag{5}$$
$$u \sqsubseteq v \implies S(u) \subseteq S(v) \tag{6}$$

This means that the mapping S plays the crucial role in terms of interpretability. In this particular case, R-Q-interpretability is the property that
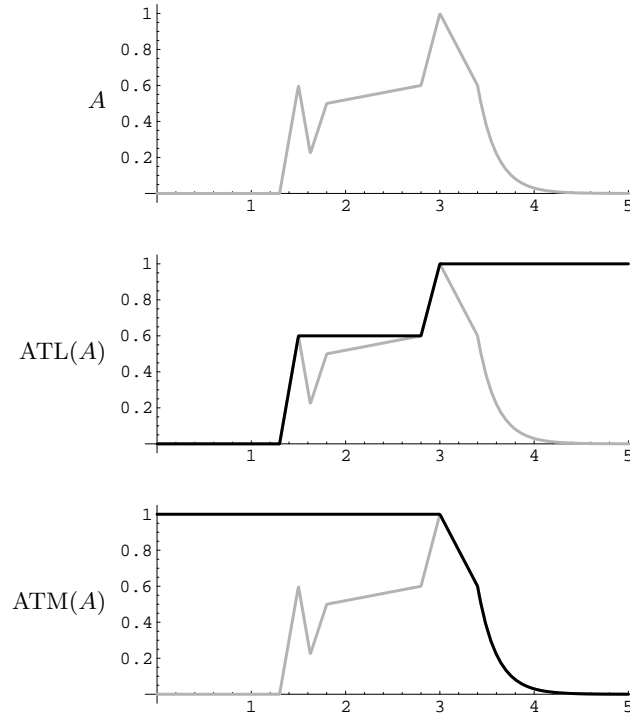

Fig. 3. A fuzzy set $A \in \mathcal{F}(\mathbb{R})$ and the results which are obtained when applying the operators ATL and ATM

an ordering or inclusion relationship between two linguistic terms is never violated by the two corresponding fuzzy sets. From (3) and (5), we can deduce the first basic necessary condition for the fulfillment of R-Q-interpretability – that the fuzzy sets associated with the three adjectives must be in proper order:

$$S(\text{``small''}) \lesssim S(\text{``medium''}) \lesssim S(\text{``large''}) \tag{7}$$

It is easy to observe that this basic ordering requirement is violated by the example shown in Fig. 4, while it is fulfilled by the fuzzy sets in Fig. 5.

In order to fully check R-Q-interpretability of V, the semantics of linguistic expressions containing an adverb ("at least" or "at most") have to be considered as well. The definition of linguistic variables does not explicitly contain any hint how to deal with the semantics of such expressions. From a pragmatic viewpoint, two different ways are possible: one simple variant is to define a separate fuzzy set for each expression, regardless whether they contain an adverb or not. As a second traditional variant, we could use fuzzy modifiers – $\mathcal{F}(X) \to \mathcal{F}(X)$ functions – for modeling the semantics of adverbs. In this example, it is straightforward to use the fuzzy modifiers introduced
Fig. 4. A non-interpretable setting

Fig. 5. An example of an interpretable setting

in Def. 4 (see [3,4,12] for a detailed justification):

$$S(\text{"at least"}\,A) = \text{ATL}\big(S(A)\big)$$
$$S(\text{"at most"}\,A) = \text{ATM}\big(S(A)\big)$$

Since it is by far simpler and easier to handle with respect to interpretability, we strongly suggest the second variant.

In case that we use the above fuzzy modifiers for modeling the two adverbs "at least" and "at most", we are now able to formulate a necessary condition for the fulfillment of R-Q-interpretability in our example.

Theorem 1. *Consider the linguistic variable V and the two relation families R and Q as defined above. Provided that the mapping S always yields a normalized fuzzy set, the following two statements are equivalent:*

(i) V is R-Q-interpretable
(ii) $S(\text{"small"}) \lesssim S(\text{"medium"}) \lesssim S(\text{"large"})$

Proof. (i)⇒(ii): Trivial (see above).

(ii)⇒(i): The following basic properties hold for all normalized fuzzy sets $A, B \in \mathcal{F}(X)$ [4]:

$$A \subseteq \text{ATL}(A) \tag{8}$$

$$A \subseteq \text{ATM}(A) \tag{9}$$

$$\text{ATL}\big(\text{ATL}(A)\big) = \text{ATL}(A) \tag{10}$$

$$\text{ATM}\big(\text{ATM}(A)\big) = \text{ATM}(A) \tag{11}$$

$$\text{ATL}\big(\text{ATM}(A)\big) = \text{ATM}\big(\text{ATL}(A)\big) = X \tag{12}$$

$$A \subseteq B \implies \text{ATL}(A) \subseteq \text{ATL}(B) \tag{13}$$

$$A \subseteq B \implies \text{ATM}(A) \subseteq \text{ATM}(B) \tag{14}$$

Since the relations $\subseteq$ and $\precsim$ are reflexive and transitive [4,5], it is sufficient to prove the relations indicated by arrows in the two Hasse diagrams (see Figs. 1 and 2).

Let us start with the ordering relation. The validity of the relations in the middle row is exactly assumption (ii). The relations in the two other rows follow directly from the following two relationships which can be proved easily using (10), (11), and (12):

$$A \precsim B \implies \text{ATL}(A) \precsim \text{ATL}(B)$$
$$A \precsim B \implies \text{ATM}(A) \precsim \text{ATM}(B)$$

The three vertical relationships in Fig. 1 follow directly from

$$\text{ATM}(A) \precsim A \precsim \text{ATL}(A)$$

which can be shown using (8), (9), (13), and (14).

The relations in the Hasse diagram in Fig. 2 follow from (8), (9), and the definition of the preordering $\precsim$ (cf. Def. 4). $\qquad\square$

Obviously, interpretability of V in this example (with respect to the families R and Q) does not fully correspond to an intuitive human understanding of interpretability. For instance, all three expressions "small", "medium", and "large" could be mapped to the same fuzzy set without violating R-Q-interpretability. The intention was to give an example which is just expressive enough to illustrate the concrete meaning and practical relevance of Def. 2.

In order to formulate an example in which R-Q-interpretability is much closer to a human-like understanding of interpretability (e.g. including separation constraints), we have to consider an extended linguistic variable

$$V' = (\text{``v2''}, G', T', X', S').$$

The extended grammar G' is given as follows:

$$\perp \qquad := \langle exp \rangle \mid \langle bounds \rangle \ ;$$
$$\langle exp \rangle \qquad := \langle atomic \rangle \mid \langle atomic \rangle \ \langle binary \rangle \ \langle atomic \rangle \ ;$$
$$\langle atomic \rangle \quad := \langle adjective \rangle \mid \langle adverb \rangle \ \langle adjective \rangle \ ;$$
$$\langle adjective \rangle := \text{"small"} \mid \text{"medium"} \mid \text{"large"} \ ;$$
$$\langle adverb \rangle \quad := \text{"at least"} \mid \text{"at most"} \ ;$$
$$\langle binary \rangle \quad := \text{"and"} \mid \text{"or"} \ ;$$
$$\langle bounds \rangle \quad := \text{"empty"} \mid \text{"anything"} \ ;$$

It is easy to see that the corresponding term set T' has the following elements: the grammar admits nine atomic expressions (three adjectives plus two adverbs times three adjectives; note that this subset coincides with T from the previous example). Hence, there are $9 + 2 \cdot 9^2 = 171$ expressions of type $\langle exp \rangle$. Finally adding the two expressions of type $\langle bounds \rangle$, the term set T' has a total number of 173 elements.

As in the previous example, we would like to use an inclusion and an ordering relation. Since the two relations $\precsim$ and $\subseteq$ are defined for arbitrary fuzzy sets, we can keep the relation family Q as it is. If we took R as defined above, R-Q-interpretability would be satisfied under the same conditions as in Th. 1. This example, however, is intended to demonstrate that partition and convexity constraints can be formulated level of linguistic expressions, too. Therefore, we extend the inclusion relation $\sqsubseteq$ as follows. Let us consider a binary relation $\sqsubseteq$ on T'. First of all, we require that $\sqsubseteq$ coincides with $\sqsubseteq$ on the set of atomic expressions ($u, v \in T$):

$$(u \sqsubseteq v) \Longrightarrow (u \sqsubseteq v) \tag{15}$$

Of course, we assume that the two binary connectives are non-decreasing with respect to inclusion, commutative, and that the "and" connective yields subsets and the "or" connective yields supersets (for all $u, v, w \in T$):

$$(v \sqsubseteq w) \Longrightarrow (u \ \text{"and"} \ v) \sqsubseteq (u \ \text{"and"} \ w) \tag{16}$$

$$(v \sqsubseteq w) \Longrightarrow (u \ \text{"or"} \ v) \sqsubseteq (u \ \text{"or"} \ w) \tag{17}$$

$$(u \ \text{"and"} \ v) \sqsubseteq (v \ \text{"and"} \ u) \tag{18}$$

$$(u \ \text{"or"} \ v) \sqsubseteq (v \ \text{"or"} \ u) \tag{19}$$

$$(u \ \text{"and"} \ v) \sqsubseteq u \tag{20}$$

$$u \sqsubseteq (u \ \text{"or"} \ v) \tag{21}$$

Next, let us suppose that "anything" is the most general and that "empty" is the least general expression, i.e., for all $u \in T'$,

$$u \sqsubseteq \text{"anything"} \quad \text{and} \quad \text{"empty"} \sqsubseteq u. \tag{22}$$

Now we can impose reasonable disjointness constraints like

$$\text{"small and at least medium"} \sqsubseteq \text{"empty"} \tag{23}$$

$$\text{"at most medium and large"} \sqsubseteq \text{"empty"} \tag{24}$$

and coverage properties:

$$\text{``small or medium''} \sqsubseteq \text{``at most medium''} \tag{25}$$

$$\text{``at most medium''} \sqsubseteq \text{``small or medium''} \tag{26}$$

$$\text{``anything''} \sqsubseteq \text{``at most medium or large''} \tag{27}$$

$$\text{``medium or large''} \sqsubseteq \text{``at least medium''} \tag{28}$$

$$\text{``at least medium''} \sqsubseteq \text{``medium or large''} \tag{29}$$

$$\text{``small or at least medium''} \sqsubseteq \text{``anything''} \tag{30}$$

Finally, let us assume that "small" and "large" are the two boundaries with respect to the ordering of the labels:

$$\text{``at most small''} \sqsubseteq \text{``small''} \tag{31}$$

$$\text{``anything''} \sqsubseteq \text{``at least small''} \tag{32}$$

$$\text{``at least large''} \sqsubseteq \text{``large''} \tag{33}$$

$$\text{``anything''} \sqsubseteq \text{``at most large''} \tag{34}$$

If we denote the reflexive and transitive closure of $\sqsubseteq$ with $\sqsubseteq'$, we can finally write down the desired family of relations:

$$R' = (\preceq, \sqsubseteq') \tag{35}$$

In order to study the R'-Q-interpretability of V', we need to define the semantics of those expressions that have not been contained in T. Of course, for the expressions in T, we use the same semantics as in the previous example, i.e., for all $u \in T$, $S'(u) = S(u)$. Further, let us make the convention that the two expressions of type $\langle \text{bounds} \rangle$ are always mapped to the empty set and the whole universe, respectively:

$$S'(\text{``empty''}) = \emptyset \qquad S'(\text{``anything''}) = X$$

The "and" and the "or" connective are supposed to be "implemented" by the intersection and union with respect to the Łukasiewicz t-norm and its dual t-conorm (for all $u, v \in T$):

$$S'(u \text{ ``and'' } v) = S'(u) \cap_{\mathbf{L}} S'(v)$$
$$S'(u \text{ ``or'' } v) = S'(u) \cup_{\mathbf{L}} S'(v)$$

Now we are able to fully characterize R'-Q-interpretability for the given example (the linguistic variable V').

Theorem 2. *Provided that S' yields a normalized fuzzy set for each adjective, V' is R'-Q-interpretable if and only if the following three properties hold together:*

1. *$S'(\text{``small''}) \lesssim S'(\text{``medium''}) \lesssim S'(\text{``large''})$*
2. *$S'(\text{``small''})$, $S'(\text{``medium''})$, and $S'(\text{``large''})$ are convex*
3. *$S'(\text{``small''})$, $S'(\text{``medium''})$, and $S'(\text{``large''})$ form a Ruspini partition*

Proof. First of all, let us assume that V' is R'-Q-interpretable. The first property follows trivially as in the proof of Th. 1. Now, taking (23) into account, we obtain from R'-Q-interpretability that

$$
\begin{aligned}
0 &\geq T_{\mathbf{L}}\big(S'(\text{``small''})(x), S'(\text{``at least medium''})(x)\big) \\
&= T_{\mathbf{L}}\big(S'(\text{``small''})(x), \text{ATL}(S'(\text{``medium''}))(x)\big) \\
&\geq T_{\mathbf{L}}\big(S'(\text{``small''})(x), S'(\text{``medium''})(x)\big),
\end{aligned}
$$

i.e. that the $T_{\mathbf{L}}$-intersection of $S'(\text{``small''})$ and $S'(\text{``medium''})$ is empty. Analogously, we are able to show that the $T_{\mathbf{L}}$-intersection of $S'(\text{``medium''})$ and $S'(\text{``large''})$ is empty, too. Since $S'(\text{``medium''}) \lesssim S'(\text{``large''})$ implies that

$$
\text{ATL}\big(S'(\text{``large''})\big) \subseteq \text{ATL}\big(S'(\text{``medium''})\big),
$$

it follows that, by the same argument as above, that the $T_{\mathbf{L}}$-intersection of $S'(\text{``small''})$ and $S'(\text{``large''})$ is empty as well. Now consider (25) and (26). R'-Q-interpretability then implies the following (for all $x \in X$):

$$
\begin{aligned}
S_{\mathbf{L}}\big(S'(\text{``small''})(x), S'(\text{``medium''})(x)\big) &= S'(\text{``at most medium''})(x) \\
&= \text{ATL}\big(S'(\text{``medium''})\big)(x)
\end{aligned}
$$

Taking (27) into account as well, we finally obtain

$$
\begin{aligned}
1 &\leq S_{\mathbf{L}}\big(S'(\text{``at most medium''})(x), S'(\text{``large''})(x)\big) \\
&= S_{\mathbf{L}}\big(S'(\text{``small''})(x), S'(\text{``medium''})(x), S'(\text{``large''})(x)\big)
\end{aligned}
$$

which proves that the $S_{\mathbf{L}}$-union of all fuzzy sets associated to the three adjectives yields the whole universe X. Since all three fuzzy sets are normalized and properly ordered, not more than two can have a membership degree greater than zero at a given point $x \in X$. This implies that the three fuzzy sets form a Ruspini partition [26].

From (31) and (33) and R'-Q-interpretability, we can infer that

$$
\begin{aligned}
\text{ATM}\big(S'(\text{``small''})\big) &= S'(\text{``small''}), \\
\text{ATL}\big(S'(\text{``large''})\big) &= S'(\text{``large''}),
\end{aligned}
$$

hence, $S'(\text{``small''})$ has a non-increasing membership function and $S'(\text{``large''})$ has a non-decreasing membership function. Both fuzzy sets, therefore, are

convex. Since the three fuzzy sets $S'($"small"$)$, $S'($"medium"$)$, and $S'($"large"$)$ form a Ruspini partition, while only two can overlap to a positive degree, we have that $S'($"medium"$)$ is non-decreasing to the left of any value x for which $S'($"medium"$)(x) = 1$ and non-increasing to the right. Therefore, by Le. 1, $S'($"medium"$)$ is convex, too.

Now let us prove the reverse direction, i.e. we assume all three properties and show that R'-Q-interpretability must hold. By (15) and the first property from Th. 2, we can rely on the fact that all correspondences remain preserved for cases that are already covered by Th. 1. Therefore, it is sufficient to show that S' preserves all relationships (16)–(34). Clearly, the preservation of (16)–(21) follows directly from elementary properties of t-norms and t-conorms [24]. The inclusions (22) are trivially maintained, since S' is supposed to map "empty" to the empty set and "anything" to the universe X. The preservation of the two disjointness conditions (23) and (24) follows from the fact that $S'($"small"$)$, $S'($"medium"$)$, and $S'($"large"$)$ form a Ruspini partition and that the first property holds. The same is true for the six coverage properties (25)–(30). Since all three fuzzy sets are convex and form a Ruspini partition, $S'($"small"$)$ must have a non-increasing membership function and $S'($"large"$)$ must have a non-decreasing membership function. Therefore, the following needs to hold:

$$\mathrm{ATM}\big(S'(\text{"small"})\big) = S'(\text{"small"})$$
$$\mathrm{ATL}\big(S'(\text{"large"})\big) = S'(\text{"large"})$$

This is a sufficient condition for the preservation of inclusions (31) and (33). Then the preservation of (32) and (34) follows from the fact, that $\mathrm{ATL}(\mathrm{ATM}(A)) = X$ for any normalized fuzzy set A (cf. (12)). Since $\sqsubseteq'$ and $\subseteq$ are both supposed to be transitive ($\sqsubseteq'$ being the transitive closure of the intermediate relation $\sqsubseteq$), the preservation of all other relationships follows instantly. □

At first glance, this example might seem unnecessarily complicated, since the final result is nothing else than exactly those common sense assumptions – proper ordering, convexity, partition constraints – that have been identified as crucial for interpretability before in several recent publications (see [8] for an overview). However, we must take into account that they are not just heuristic assumptions here, but necessary conditions that are enforced by intuitive requirements on the level of linguistic expressions. From this point of view, this example provides a sound justification for exactly those three crucial assumptions.

Now the question arises how the three properties can be satisfied in practice. In particular, it is desirable to have a constructive characterization of the constraints implied by requiring R'-Q-interpretability. The following theorem provides a unique characterization of R'-Q-interpretability under the assumption that we are considering real numbers and fuzzy sets with continuous membership functions – both are no serious restrictions from the practical

point of view. Fortunately, we obtain a parameterized representation of all mappings S' that maintain R'-Q-interpretability.

Theorem 3. *Assume that X is a connected subset of the real line and that S', for each adjective, yields a normalized fuzzy set with continuous membership function. Then the three properties from Th. 2 are fulfilled if and only if there exist four values $a, b, c, d \in X$ satisfying $a < b \leq c < d$ and two continuous non-decreasing $[0, 1] \to [0, 1]$ functions f_1, f_2 fulfilling $f_1(0) = f_2(0) = 0$ and $f_1(1) = f_2(1) = 1$ such that the semantics of the three adjectives are defined as follows:*

$$S'(\text{``small''})(x) = \begin{cases} 1 & \text{if } x \leq a \\ 1 - f_1\left(\frac{x-a}{b-a}\right) & \text{if } a < x < b \\ 0 & \text{if } x \geq b \end{cases} \tag{36}$$

$$S'(\text{``medium''})(x) = \begin{cases} 0 & \text{if } x \leq a \\ f_1\left(\frac{x-a}{b-a}\right) & \text{if } a < x < b \\ 1 & \text{if } b \leq x \leq c \\ 1 - f_2\left(\frac{x-c}{d-c}\right) & \text{if } c < x < d \\ 0 & \text{if } x \geq d \end{cases} \tag{37}$$

$$S'(\text{``large''})(x) = \begin{cases} 0 & \text{if } x \leq c \\ f_2\left(\frac{x-c}{d-c}\right) & \text{if } c < x < d \\ 1 & \text{if } x \geq d \end{cases} \tag{38}$$

Proof. It is a straightforward, yet tedious, task to show that the fuzzy sets defined as above fulfill the three properties from Th. 2. Under the assumption that these three properties are satisfied, we make the following definitions:

$$a = \sup\{x \mid S'(\text{``small''})(x) = 1\}$$
$$b = \inf\{x \mid S'(\text{``medium''})(x) = 1\}$$
$$c = \sup\{x \mid S'(\text{``medium''})(x) = 1\}$$
$$d = \inf\{x \mid S'(\text{``large'})(x) = 1\}$$

The two functions f_1, f_2 can be defined as follows:

$$f_1(x) = S'(\text{``medium''})\big(a + x \cdot (b - a)\big)$$
$$f_2(x) = S'(\text{``large''})\big(c + x \cdot (d - c)\big)$$

Since all membership functions associated with adjectives are continuous, the functions f_1 and f_2 are continuous. Taking the continuity and the fact that the three fuzzy sets associated to the adjectives form a Ruspini partition into

account, it is clear that the following holds:

$$S'(\text{``small''})(a) = 1$$
$$S'(\text{``small''})(b) = S'(\text{``small''})(c) = S'(\text{``small''})(d) = 0$$

$$S'(\text{``medium''})(b) = S'(\text{``medium''})(c) = 1$$
$$S'(\text{``medium''})(a) = S'(\text{``medium''})(d) = 0$$

$$S'(\text{``large''})(d) = 1$$
$$S'(\text{``large''})(a) = S'(\text{``large''})(b) = S'(\text{``large''})(c) = 0$$

These equalities particularly imply that $f_1(0) = f_2(0) = 0$ and $f_1(1) = f_2(1) = 1$ holds. As a consequence of convexity and Le. 1, we know that the membership function of $S'(\text{``medium''})$ to the left of $b$ is non-decreasing. Analogously, we can infer that the same is true for $S'(\text{``large''})$ to the left of d. Therefore, f_1 and f_2 are non-decreasing. To show that the three representations (36)–(38) hold is a routine matter. □

5 Applications

5.1 Design Aid

As long as the top-down construction of small fuzzy systems (e.g. two-input single-output fuzzy controllers) is concerned, interpretability is usually not such an important issue, since the system is simple enough that a conscious user will refrain from making settings which contradict his/her intuition.

In the design of complex fuzzy systems with a large number of variables and rules, however, interpretability is a most crucial point. Integrating tools which guide the user through the design of a large fuzzy system by preventing him/her from making non-interpretable settings accidentally are extremely helpful. As a matter of fact, debugging of large fuzzy systems becomes a tedious task if it is not guaranteed that the intuitive meanings of the labels used in the rule base are reflected in their corresponding semantics.

To be more precise, our goal is not to bother the user with additional theoretical aspects. Instead, the idea is to integrate these aspects into software tools for fuzzy systems design, but not necessarily transparent for the user, with the aim that he/she can build interpretable fuzzy systems in an even easier way than with today's software tools. Theorem 3 gives a clue how this could be accomplished. This result, for one particular example, clearly identifies how much freedom one has in choosing interpretable settings. The example is not quite representative, since three linguistic expressions are a quite restrictive assumption. However, the extension to an arbitrary finite number of such expressions is straightforward, no matter whether we consider such a typical "small"-"medium"-"large" example or a kind of symmetric setting (e.g. "neg. large", "neg. medium", "neg. small", "approx. zero", "pos. small",

"pos. medium", "pos. large") as it is common in many fuzzy control applications. In all these cases, the requirements for interpretability are similar and, by Th. 3, the resulting set of degrees of freedom is an increasing chain of values that mark the beginning/ending of the kernels of the fuzzy sets and a set of continuous non-decreasing functions that control the shape of the transitions between two neighboring fuzzy sets. While linear transitions are common and easy to handle, smooth transitions by means of polynomial functions with higher degree may be beneficial in some applications as well.

As simple examples, the following three polynomial $[0, 1] \rightarrow [0, 1]$ functions of degrees 1, 3, and 5 perfectly serve as transition functions in the sense of Th. 3. They produce membership functions that are continuous (p_1), differentiable (p_3), and twice differentiable (p_5), respectively:

$$p_1(x) = x$$
$$p_3(x) = -2x^3 + 3x^2$$
$$p_5(x) = 6x^5 - 15x^4 + 10x^3$$

Figure 6 shows examples of interpretable fuzzy partitions with three fuzzy sets using the transition functions p_1, p_3, and p_5.

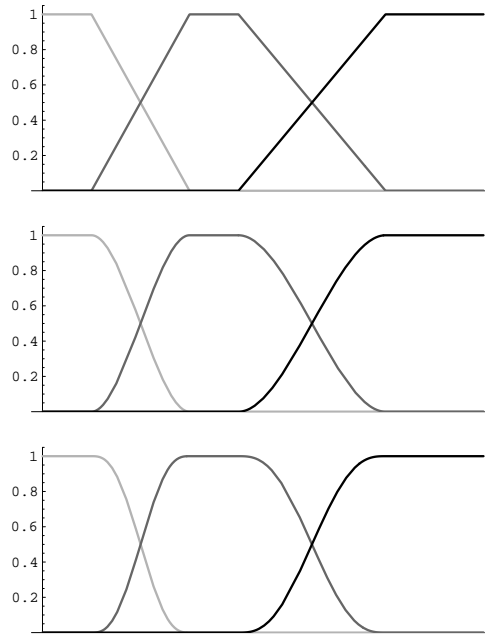

Fig. 6. Three interpretable fuzzy partitions with polynomial transitions of degree 1 (top), 3 (middle), and 5 (bottom)

5.2   Tuning

Automatic design and tuning of fuzzy systems has become a central issue in machine learning, data analysis, and the identification of functional dependencies in the analysis of complex systems. In the last years, a vast number of scientific publications dealt with this problem. Most of them, however, disregarded the importance of interpretability – leading to results which are actually black-box functions that do not provide any meaningful linguistic information (typical pictures like in Fig. 4 can be found in an enormous number of papers).

One may argue that proper input-output behavior is the central goal of automatic tuning. To some extent, this is true; however, as stated already in Sect. 1, this is not the primary mission of fuzzy systems.

Again, Th. 3 gives a clear indication how the space of possible solutions among interpretable settings may be parameterized – by an ascending chain of transition points (given a set of transition functions). Note that this kind of parameterization even leads to a reduction of the search space. Parameterizing three trapezoidal fuzzy sets independently requires a total number of twelve parameters and most probably leads to difficulty interpretable results. Requiring interpretability (as described in the previous section) leads to a set of only four parameters. It is true that such a setting is much more restrictive. However, in our opinion, it is not necessarily the case that requiring interpretability automatically leads to a painful loss of accuracy. The requirement of interpretability implies more constraints that have to be taken into account and, therefore, is more difficult to handle for many tuning algorithms, no matter whether we consider genetic algorithms, fuzzy-neuro methods, or numerical optimization. As a recent investigation has shown, it is indeed possible to require interpretability while, at the same time, maintaining high accuracy and robustness [22]. Many other studies have also come up with tuning algorithms that produce interpretable *and* accurate results [2,7,13,17,35].

5.3   Rule Base Simplification

The examples in Sect. 4 used an inclusion relation $\sqsubseteq$ and its counterpart on the semantical side – the inclusion relation $\subseteq$. Both relations are preorderings which particularly implies that their symmetric kernels are equivalence relations. As easy to see, the relation $\subseteq$ is even an ordering on $\mathcal{F}(X)$, which implies that the symmetric kernel is the crisp equality relation, i.e. $A \subseteq B$ and $B \subseteq A$ hold together if and only if the two membership functions coincide exactly.

Now let us assume that we are given a linguistic variable V and two relation families R and Q, where R contains an inclusion relation $\sqsubseteq$ and Q contains its counterpart $\subseteq$. If we have two linguistic labels u and v for which $u \sqsubseteq v$ and $v \sqsubseteq v$ hold, R-Q-interpretability guarantees that the inclusions $S(u) \subseteq S(v)$ and $S(v) \subseteq S(u)$ hold, i.e. $u \sqsubseteq v$ and $v \sqsubseteq v$ are sufficient

conditions that the membership functions of $S(u)$ and $S(v)$ are equal. This means that the equivalence relation defined as (for two $u, v \in T$)

$$(u \equiv v) \iff (u \sqsubseteq v \text{ and } v \sqsubseteq u)$$

may be considered as a set of *simplification rules*, while R-Q-interpretability corresponds to the validity of these rules on the semantical side.

Let us recall the second example (linguistic variable V' defined as in Sect. 4). The two inequalities (25) and (26) together imply

$$\text{"small or medium"} \equiv \text{"at most medium"}.$$

This could be read as a replacement rule

$$\text{"small or medium"} \longrightarrow \text{"at most medium"},$$

with the meaning that, in any linguistic expression, "small or medium" can be replaced by "at most medium". If we assume interpretability, we can be sure that this replacement is also semantically correct. If we incorporate as many reasonable relationships in the relation $\sqsubseteq$ as possible such that interpretability can still be fulfilled, we are able to provide a powerful set of simplification rules.

Of course, very simple grammars do not necessitate any simplification. However, if we have to consider very complex rule bases like they appear in grammar-based rule base optimization methods (e.g. inductive learning [28–31] or fuzzy genetic programming [19,20]), simplification is a highly important concern. The methodology presented here allows to deal with simplification in a symbolic fashion – assuming interpretability – without the need to consider the concrete semantics of the expressions anymore.

6   Conclusion

This chapter has been devoted to the interpretability of linguistic variables. In order to approach this key property in a systematic and mathematically exact way, we have proposed to make implicit relationships between the linguistic labels explicit by formulating them as (fuzzy) relations. Then interpretability corresponds to the preservation of this relationships by the associated meaning. This idea has been illustrated by means of two extensive examples. These case studies have demonstrated that well-known common sense assumptions about the membership functions, such as, ordering, convexity, or partition constraints, have a sound justification also from a formal linguistic point of view. In contrast to other investigations, the model proposed in this chapter cannot just be applied to simple fuzzy sets, but also allows smooth integration of connectives and ordering-based modifiers.

By characterizing parameterizations which ensure interpretability, we have been able to provide hints for the design and tuning of fuzzy systems with

interpretable linguistic variables. Finally, we have seen that interpretability even corresponds to the fact that symbolic simplification rules on the side of linguistic expressions still remain valid on the semantical side.
